- Given some data (x_1, x_2, \ldots, x_N)
- Represent them *compactly*
- Frequently done as part of exploratory analysis of your data
- Sometimes also done to make subsequent ML algorithms work better (e.g. make your classifier better)

< □ > < □ > < □ > < □ > < □ > < □ >

- Classic algorithm. Workhorse and useful in many, many contexts
- Very simple. Start with a random number of centroids
- Assign points to each centroid based on proximity
- Recalculate the new centroids from all points assigned to each
- Repeat till no change of assignment of points happen

- Classic algorithm. Workhorse and useful in many, many contexts
- Very simple. Start with a random number of centroids
- Assign points to each centroid based on proximity
- Recalculate the new centroids from all points assigned to each
- Repeat till no change of assignment of points happen

- Classic algorithm. Workhorse and useful in many, many contexts

- $\bullet~\mbox{Given}$ a set of data points $(\mathbf{x_1}, \mathbf{x_2}, \ldots, \mathbf{x_N})$
- Model them using a set of Gaussians centered around different points in the space
- Model the distribution as $p(\mathbf{x}) = \sum_{i=1}^{K} \phi_i \mathcal{N}(\mu_{\mathbf{i}}, \boldsymbol{\Sigma_{\mathbf{i}}^2})$
- Evaluate the fit by estimating the data likelihood $p(x|\theta),$ for a given parameter setting θ
- What are the parameters that determine the fit?

Overview

3 Learning Latent Representations

イロト イヨト イヨト イヨト

- \bullet Given a set of data points $(\mathbf{x_1}, \mathbf{x_2}, \ldots, \mathbf{x_N})$
- Figure out if a new data point is anomalous
- Attack, Denial of Service, Virus, Failure, ...

Anomaly Detection

Jan 31, 2018 10 / 19

э

Anomaly Detection

- kNN
- Local outlier rejection
- One-class SVM

< □ > < 同 > < 回 > < 回 > < 回 >

Overview

э

< □ > < 同 > < 回 > < 回 > < 回 >

- Very popular in Natural Language Processing
- Latent Semantic Analysis
- Dimensionality Reduction (e.g. PCA)
- Independent Component Analysis
- Word-embeddings (e.g. Word2Vec)
- Autoencoders

Latent Semantic Analysis

- Consider the Term-Document matrix
- Approximate this with a low-rank approximation
- This helps eliminate **noise** and **merge** similar words

- d1: Romeo and Juliet.
- d2: Juliet: O happy dagger!
- d3: Romeo died by dagger.
- d4: ?Live free or die?, that?s the New-Hampshire?s motto.
- d5: Did you know, New-Hampshire is in New-England.

Latent Semantic Analysis

Documents >>	d1	d2	d3	d4	d5
romeo	1	0	1	0	0
juliet	1	1	0	0	0
happy	0	1	0	0	0
dagger	0	1	1	0	0
live	0	0	0	1	0
die	0	0	1	1	0
die	0	0	0	1	0
new-hampshire	0	0	0	1	1

Table: Document-Term matrix

Jan 31, 2018 15 / 19

3

- Given a k-dimensional dataset with possibly correlated dimensions
- Project the data into a set of orthogonal dimensions that are much smaller than k
- Useful for exploratory data analysis
- Dimensionality reduction prior to modeling using another ML algorithm

- Attempts to decompose a multi-variate signal into independent, additive, non-gaussian components
- Example: Separating individual sources from a mixed audio signal (cocktail party effect)
- As long as the independence assumptions are valid, produces good results
